;;; zos.inc
;;; a lightweight, small-footprint, preemptively multitasking RTOS for Microchip
;;; Technology's entire enhanced midrange 8-bit PIC microcontroller family:
;;; jobs (up to 5) are never allowed to manipulate the BSR directly, as that is
;;; the prerogative of zOS (it being used as the current job #) and the bank may
;;; never end up greater than zOS_NUM in user space with interrupts enabled!!!
;;; memory footprint:
;;; ~613 14-bit words for base RTOS i.e. main() starts at 0x0263
;;; ~511 words if zOS MIN is defined to omit FRK/EXE/FND (thus SWI#4~7=zOS YLD)
;;; SRAM footprint:
;;; 86 bank-0 bytes claimed by RTOS, 30 bytes of stack scratch space relocatable
                                            local bytes/job (+any heap, besides
;;; available bytes
                      possible jobs with
;;; on PIC device
                       80 bytes RAM each
                                             2 global bytes) if zOS_NUM set to 5

                                 ;} // zOS_MAN()
        endm
;;; zOS_CLC is an extension of the zOS_MAN() job manager shell into an rpn calc-
;;; ulator, as an example of how to use and customize the above console macros
;;;
;;; Note: because the max call depth of zOS_MON's ISR is nonzero (1), the max
;;; call depth for jobs in a system invoking these macros is reduced from 3 to 2
;;;
;;; (job 0)
;;; zOS CLC is invoked with an optional isr routine (for any custom extensions):
;;; First a jump over the clcisr code ends the macro expansion
;;; zOS_MAN is invoked with all the zOS_CON arguments and its clcisr address:
      zOS_MON is invoked with all the zOS_CON arguments (and the clcisr address)
;;;
;;;
       First a jump over zOS_MON's monisr and all its support functions (no task)
;;;
       zOS_INP is invoked with all the zOS_CON arguments (and monisr's address)
;;;
        Immediately a near branch to rxdecl over the rxtask and rxisr code:
;;;
        When run, rxtask first calls any code at nonzero optadrh:optadrl address
;;;
        then jumps to the mandatorily nonzero tskadrh:tskadrl task of zOS_CON
;;;
        When handling an interrupt, rxisr either handles a received character or
;;;
        jumps to the mandatorily nonzero isradrh:isradrl isr address of zOS_CON
;;;
        and if a received character the ISR in this case jumps to nonzero monisr
;;;
        Unlike most declarations, rxdecl not only declares but launches, tweaks:
;;;
        zOS_CON is invoked with the port, rate, rtsflag, heartbeat, pin arguments:
;;;
         Immediately a near branch to decl over the task and isr code:
;;;
         When run, task initializes the global pair, circular buffer and greets
;;;
         (if the pair was still zero) then cedes the core awaiting a character
;;;
         which it then sends and loops back (to the zOS_INP task, not its own!)
```

```
When handling an interrupt, isr handles the heartbeat and TimerO stuff
;;;
;;;
         (if hardware) else assumes that a software interrupt is a char to send
;;;
         since any other applicable situation was handled by rxisr pre-jump
;;;
        end of zOS_CON expansion
;;;
        zOS_LAU then immediately assigns a job bank to the zOS_CON instance and
;;;
        uses FSR1 to set locals isradrh:isradrl,tskadrh:tskadrl,optadrh:optadrl
;;;
        to values zOS_CON just put in zOS_ARG1:zOS_ARG0, FSR0 (left at latter)
;;;
       at which point it overwrites the Program Counter and HanDle fields with
       rxtask, ISR field with rxisr and RX HWI mask using FSR0 (left at SWI)
;;;
;;;
       end of zOS_INP expansion
      FSR1 (pointing to optadrh:optadrl) then gets the address of the ensuing
;;;
     mantask code (no ISR) which is then jumped over
;;;
     end of zOS_MON expansion
    end of zOS_MAN expansion
;;; end of zOS_CLC expansion
;;; Since the end of zOS_INP, FSRO has been pointing to the job information byte
;;; for the SWI mask that the job is to listen on for characters to output, so
;;; movwi 0[FSR0] with w set to the appropriate value: 8, 16, 32, 64 or 128
